---

**Problem 1.0:****a)**

$L_1 = \{0^a 1^b \mid a \text{ divides } b\}$  is equivalent to  $L_1 = \{0^a 1^{am} \mid m \geq 0\}$ .

*Proof.*

Towards contradiction:

- Assume  $L_1$  is CF.
- By pumping lemma  $\exists$  pumping length  $p$ .
- Let  $s = 0^k 1^{km}$  s.t.  $|s| \geq p$ .
- By pumping lemma  $0^k 1^{km} = xyzuv$ 
  - 1)  $|yzu| \leq p$
  - 2)  $|yu| > 0$

**Cases:**

- 1)  $yzu = 0^a$ ,  $1 \leq k \leq p$ . Then  $xy^2zu^2v = 0^{k'} 1^{nk'}$

The number of 1's does not change therefore:

$$k' n = km \tag{1.1}$$

$$n = \frac{k}{k'} m \tag{1.2}$$

$$n = \frac{k}{k + \alpha} m \tag{1.3}$$

$n$  has to be an integer but  $k' > k$  therefore  $n \notin \mathbb{N}$ .

2)  $yzu = 1^\alpha$ ,  $1 \leq k \leq p$ . Then  $xzv = 0^{\frac{k'}{n}} 1^{k'}$

The number of 0's does not change therefore:

$$\frac{k}{m} = \frac{k'}{n} \quad (1.4)$$

$$kn = k'm \quad (1.5)$$

$$n = \frac{k'}{k}m \quad (1.6)$$

$$n = \frac{k - \alpha}{k}m \quad (1.7)$$

$n$  has to be an integer but  $k' < k$  therefore  $n \notin \mathbb{N}$

3)  $yzu = 0^\alpha 1^\beta$ ,  $1 \leq \alpha + \beta \leq p$  then  $xy^2zv^2u = 0^{p+\alpha} 1^{pm+\beta}$

$$\frac{a}{b} = m \quad (1.8)$$

$$\frac{pm + \beta}{p + \alpha} = m \quad (1.9)$$

$$pm + \beta = pm + m\alpha \quad (1.10)$$

$$\beta = m\alpha \quad (1.11)$$

□

**b)**

Let  $L = \{a^n b^n \mid n \geq 0\}$  then  $\tilde{L} = \{a^n b^{2n} a^n \mid w \in L \text{ or } w^R \in L\}$

*Proof.* Towards contradiction assume that  $\tilde{L}$  is context-free.

- By pumping lemma  $\exists$  pumping length  $p$ .
- Let  $w \in \tilde{L}$ ,  $w = a^p b^{2p} a^p$ ,  $|w| \geq p$
- By pumping lemma  $a^p b^{2p} a^p = xyzuv$
- $|yzu| \leq p$
- $yu > 1$

**Cases:**1)  $yzu = a^\alpha$  on the left,  $1 \leq \alpha \leq p$ 

$$xzv = a^{p-\alpha}b^{2p}a^p \notin \tilde{L}$$

2)  $yzu = a^\alpha$  on the right,  $1 \leq \alpha \leq p$ 

$$xzv = a^pb^{2p}a^{p-\alpha} \notin \tilde{L}$$

3)  $yzu = b^\beta$ ,  $1 \leq \beta \leq p$ 

$$xzv = a^pb^{2p-\beta}a^p \notin \tilde{L}$$

□

**Problem 2.0:****a)**

We have two stacks  $S_1$  and  $S_2$ . First the elements of a string must be pushed onto  $S_1$ . Once all elements are in  $S_1$  push all but the bottom most element onto  $S_2$ . Now the stacks will represent a window into two elements of the input string, the top of  $S_1$  will be the element on the left and the top of  $S_2$  will be the element on the right. To simulate head movement of Turing machine T we define left and right movement by pushing and popping from stacks of multi-stack machine M.

**Move head to the right***Push<sub>S<sub>1</sub></sub>(Pop<sub>S<sub>2</sub></sub>)***Move head to the right and replace element with  $\beta$** *Pop<sub>S<sub>1</sub></sub>, Push<sub>S<sub>1</sub></sub>( $\beta$ ), Push<sub>S<sub>1</sub></sub>(Pop<sub>S<sub>2</sub></sub>( $\alpha$ ))***Move head to the right and write  $\beta$** *Push<sub>S<sub>1</sub></sub>( $\beta$ ), Push<sub>S<sub>1</sub></sub>(Pop<sub>S<sub>2</sub></sub>( $\alpha$ ))***Move head to the left***Push<sub>S<sub>2</sub></sub>(Pop<sub>S<sub>1</sub></sub>( $\alpha$ ))***Move head to the left and replace element with  $\beta$** *Pop<sub>S<sub>1</sub></sub>, Push<sub>S<sub>2</sub></sub>( $\beta$ )***Move head to the left and write  $\beta$** *Push<sub>S<sub>2</sub></sub>(Pop<sub>S<sub>1</sub></sub>( $\alpha$ )), Push<sub>S<sub>2</sub></sub>( $\beta$ )*

The states of machine M are equal to the states of T. Transitioning between states is done using the  $\delta$  function of machine T. An accepting state of this machine would be conditioned on a specific configuration of the elements in the stacks and we can move left to right to determine if the configuration is valid and then transitioning on to an accept state that is in T.

b)

We simulate three stacks using a turing machine T. In class we showed that a multi-tape turing machine can be simulated using a single tape. For simplicity we use multiple separate tapes. We have an input tape to store the input string and  $t_1$ ,  $t_2$ , and  $t_3$  each tape for one stack. We are given machine M with three stacks  $S_1$ ,  $S_2$ , and  $S_3$ . Let  $x = x_1x_2 \dots x_n$  be the input string.

### Starting States of Stacks and Tapes

Each stack has a starting state with an end of stack symbol on it. Machine T has the input  $x$  on its input tape and each tape  $t_i$  will have the corresponding stack symbol as its first symbol.

### Stack Operations

Upon reading  $x_i$  machine M can:

- 1)  $Push_{S_i}(x_i)$  - Push  $x_i$  onto stack  $S_i$  for  $i \in \{1, 2, 3\}$
- 2)  $Pop_{S_i}$  - Pop element off of  $S_i$ .
- 3)  $Push_{S_i}(Pop_{S_j})$ ,  $i \neq j$  - Pop and element of one stack and push to another.

### Equivalent Tape Operations

Each operation corresponds to the operations defined above respectively. Upon reading  $x_i$  machine T:

- 1) Move head to end of tape  $t_i$ , when first  $\sqcup$  is under head, and write  $x_i$  onto it.
- 2) Move head to end of tape  $t_i$ , then move the the left by one and write  $\sqcup$ .
- 3) Move to end of tape  $t_j$  and the left by one. Then move to end of  $t_i$  and write symbol under head of  $t_j$  onto  $t_i$ .

The states of machine T are equal to the states of machine M. Transitions between states in T follow the  $\delta$  function of machine M. T accepts if after processing string  $x$  it is in the accept states of machine M.

In part a) we showed that a Turing machine is no more powerful than a 2 stack PDA. In part b) we showed that a 3-stack machine is no more powerful than a TM machine. Therefore a 3-stack PDA is no more powerful than a 2-stack PDA.
